

Het Koradia

1. Here we can see the throughput was super high in the middle around 524,288 bytes. Then the total throughput drops till it plateaus at around 110 Mb/s.
2. One thing that could affect the speed is the buffer size which the process is allocated. A small buffer size could cause the data in the buffer to be erased before writing with new data. This could cause the client and server to send more requests to each other which could increase time to reply and send an answer back.
